SOLVING THE MOBILE TESTING CONUNDRUM

Even though mobile testing is complex, it can be done successfully with the correct strategy.

A sound mobile test automation strategy must include test automation frameworks, real devices, and emulators and simulators.
A global overview by WeAreSocial.com (2017) revealed that more than half of the world’s web traffic now comes from mobile devices. Additionally, Gartner states that by 2018, more than 50 percent of users will go to a tablet or smartphone first for all online activities. So, it is not surprising that today’s software development is based on a mobile-first, even if it is not mobile-only, imperative. But for all these dramatic changes, developers still struggle when it comes to mobile testing. In this feature, I set out the factors to consider when building an effective mobile test automation strategy and weigh up the benefits and disadvantages of popular test automation frameworks.

There are many factors that can make or break the success of a mobile app. For example, consider device fragmentation. Gartner says that in Q4 2016 there were 432 million smartphones sold in the world. Of that 432 million, 352 million run Android and 77 million run iOS. Those are just new phones – there are hundreds of millions of other devices running older firmware. When your app needs to work across most of these devices, it can become a serious burden for testers.

Another factor that contributes to this complexity is the device itself: varying screen and device sizes, resolutions and orientations. Next, we have multiple app types, such as web, hybrid and native. These multitudes of devices operate differently on various device and OS combinations. Finally, you have users all over the world in different regions that must be tested for translations, timezones and targets. These factors make testing with mobile a challenge. The good news is that even though mobile testing is complex, it can be done successfully with the correct strategy. When building a mobile testing strategy, there are three key areas of focus:

1. Real device testing
2. Emulator and simulator testing
3. Test automation frameworks

By focusing on these three areas, organizations will thrive in the fast-paced world of mobile software development.

**SCALE CONTINUOUS TESTING WITH EMULATORS AND SIMULATORS**

For several years, the use of emulators and simulators to test mobile applications has been met with some resistance. This is based on the perception that if you’re not testing on a real device, you’re not testing at all.
Although real devices give more accurate test results, using them alone is not ideal for continuous testing and continuous delivery. Due to budget issues, some organizations forgo real devices altogether as they’re too expensive, and instead opt for emulators and simulators. But the reality is that effective and efficient mobile app development requires both emulators/simulators and real devices.

An emulator, as the term suggests, emulates the device software and hardware on a desktop PC, or as part of a cloud testing platform. The Android (SDK) emulator is one example.

A simulator, on the other hand, delivers a replica of a phone’s user interface, and does not represent its hardware. It does not run the real device OS; rather, it’s a partial reimplementation of the operating system written in a high-level language. The iOS simulator for Apple devices is one such example.

Emulators give teams the ability to implement parallel testing and test automation via external frameworks like Appium or Espresso. Selenium revolutionized the world of web app testing by pioneering browser-based test automation. Today, Appium is its counterpart for mobile app testing. Appium uses the same WebDriver API that powers Selenium, and enables automation of native, hybrid, and mobile web apps. This brings huge improvements in the speed of tests for organizations coming from the manual world of testing on real devices. Emulators enable parallel testing in a way that can’t be achieved with devices in a lab. Because tests on emulators are software-defined, multiple tests can be run on tens of emulators at the click of a button without
having to manually prepare each emulator for the tests. Further, automation is easier with emulators as the tests can be executed without manual intervention, and be controlled remotely.

**DEVOPS, CONTINUOUS TESTING AND CONTINUOUS DELIVERY**

The speed of release and change demands that mobile development is agile. Mobile requires that continuous testing (the process of executing automated tests as part of the software delivery pipeline to obtain immediate feedback on the business risks) is a key component to the overall regression testing strategy. In order to properly build out a mobile regression testing strategy, it is imperative that the dev/test teams are well equipped with the following:

- **A comprehensive web and mobile testing platform**
  building a test lab from the ground up is timely and expensive. The best option is to use a cloud-based, device lab solution that provides an extensive choice of real devices, as well as emulators and simulators. This should also include parallel testing so that test execution can be done in a shorter amount of time.

- **Highly scalable, highly available solution**
  developers and testers need to ensure that the infrastructure for mobile testing allows the team to expand coverage as the test suite grows. The goal is to decrease test execution time while providing fast feedback, and to ensure that the team spends less time chasing false failures and more time on actual testing and defect remediation.

- **CI/CD optimization**
  in order for the regression testing efforts to keep up with the fast pace of continuous delivery, the process must have a tight integration with the development workflow and mobile app delivery pipeline. The goal is to eliminate any unnecessary manual steps, and promote an automation-first philosophy throughout the testing process.

Although mobile regression testing can be a challenge, the risks of flaky software can be reduced by making sure your organization has the right strategy in place.

**Mobile test automation frameworks**

Test automation frameworks are an integral part of mobile test automation. There are many test automation frameworks freely available, but the top
mobile testing frameworks are Appium, Espresso and XCUITest. Sauce Labs recently conducted a survey of teams using test automation frameworks for mobile app testing. The survey found that 63 percent of the participants use the Appium framework, while 31 percent didn’t use any test automation framework at all. Since Appium is based on Selenium (the popular open source functional testing framework), it wasn’t a huge surprise that most of the users surveyed were using Appium. But the main question is why is it that over 30 percent of users were not using some sort of testing framework? The answer lies in the implementation, or lack of a mobile testing strategy.

When implementing a mobile testing strategy, it is very important to understand

1. The skillset of the test automation team and

2. The framework that best fits the organization’s preferred development methodology.

---

**TESTER AUTOMATION SKILL SET**

When evaluating frameworks, it’s important to understand the technical background of your team. Some frameworks take a “black box” test approach, which is typically best for traditional test automation engineers. While other frameworks take a “white box” approach suitable for developers. There are pros and cons to each framework, but let’s explore the top three.

**Appium**

From Appium.io:

“Appium is an open-source tool for automating native, mobile web, and hybrid applications on iOS and Android platforms. Native apps are those written using the iOS, Android, or Windows SDKs. Mobile web apps are web
apps accessed using a mobile browser (Appium supports Safari on iOS and Chrome or the built-in ‘Browser’ app on Android). Hybrid apps have a wrapper around a “webview” – a native control that enables interaction with web content.” The key advantages of Appium are:

- A single, cross-platform framework for both Android and iOS
- The ability to automate mobile web, native and hybrid applications
- Tests can be run on emulators, simulators and real devices

Supports any language supported by Selenium, such as Ruby, Java, JavaScript, Python, C#, etc.

Appium is one of the more popular testing frameworks for those organizations that typically have testers who have worked with Selenium and are currently making the transition to mobile development. Since Appium is a black box type framework, the tester has less insight into the code, and the focus of testing is limited to what is exposed by the mobile application under test.

### WHAT MOBILE AUTOMATION FRAMEWORK DO YOU USE?

<table>
<thead>
<tr>
<th>Framework</th>
<th>Percentage</th>

**Espresso**

The Espresso testing framework provides a set of APIs to build UI tests to test user flows within an app. These APIs let you write automated UI tests that are concise and that run reliably. Espresso is well-suited for writing white box-style automated tests, where the test code utilizes implementation code details from the app under test.
The key advantages of Espresso are:

Espresso is that it is super-fast and reliable. It is fully integrated with Android Studio, the preferred mobile development platform for Android apps. It’s based on Java or JUnit, which many android developers are familiar with. Since Espresso is integrated with Android Studio, it’s automatically CI/CD ready, allowing teams to easily incorporate their test with existing continuous integration & delivery tools and frameworks.

Another advantage of the Espresso test framework is that it automatically provides updates to the latest and greatest features of the Android operating system. This helps keep testing in sync with new features and improvements as they become available. In addition, Espresso’s integration with Android Studio provides backward and forward compatibility. This allows teams to ensure their app works on previous releases of the Android OS.

A huge benefit for testing with the Espresso framework is automatic synchronization. Many testers struggle with UI testing reliability because of waits for elements to become visible or active. With other frameworks, the developer must write code to manage these issues. Once the object appears, Espresso handles the execution on that object for you. This results in less “flakiness” of test scripts and more reliable regression test suites.

Espresso, XCUI Test and Appium are all useful frameworks for writing tests for mobile applications. But a question to be answered is really what is the best framework for the job. No one tool is applicable to all situations. Espresso and XCUI Test are great tools for mobile testing when source code is available and the developer is working in an IDE. Appium is the mobile application testing tool to use when all that is available is the API or APP deployment artifacts. And all come with tradeoffs. Finding the right test automation framework for the right job is a hard determination to make.

**XCUI Test**

XCUI Test is the automation framework that ships with Apple’s XCode. The XCTest framework lets iOS app developers create and run unit tests, performance tests and UI tests for XCode projects. It provides developers with capabilities similar to those found in Espresso. However, Espresso is dedicated to code written for the Android operating system and XCUI Test is dedicated to Objective-C and Swift code that runs under iOS.
XCUITest was created specifically for testing iOS apps and is maintained by Apple. This ensures that developers get the best support from the Apple developer community as well as the latest updates for new releases on iOS. Additionally, the ability to run unit, UI and performance tests allows more comprehensive testing within a single framework.

</tbody>
</table>

If the development of the app is strictly for iOS then the developer has everything at their fingertips. If the app is cross platform using XCUITest it can be a slight disadvantage - for instance, the issue of developer skill set. Tests written for XCUITest can only be written in Objective-C or Swift code. A team that has developers experienced in Java, JavaScript, or any language that Selenium supports must now learn another scripting language and manage two frameworks. This is another reason Appium has become popular with test automation engineers that support multiple mobile app platforms.

Testing frameworks are a key component of mobile application development. With Agile, DevOps, continuous testing and integration, developers and test automation engineers must continue to develop, test and execute at a rapid pace.

Frameworks such as Espresso, XCUITest and Appium make automation easier to scale for the SMBs to the enterprise.
CONCLUSION

A sound mobile test automation strategy must include test automation frameworks, real devices, and emulators and simulators. Each component is critical to the rapid release of well tested software.

Agile, DevOps and continuous testing are the norm. Mobile software development naturally follows this paradigm. Implementing these components as part of the mobile testing strategies will increase the chances of successful releases and decrease the chances of poor app quality.
Sauce Labs provides the world’s largest cloud-based platform for automated testing of web and mobile applications. Sauce Labs runs over 1.5 million tests per day, providing most up to date testing trends along with instant access to all the device and OS combinations listed in this report. Sauce Labs provides the testing for mobile web, hybrid and native apps. Its award-winning service eliminates the time and expense of maintaining an in-house testing infrastructure, freeing development teams of any size to innovate and release better software, faster.

Sauce Labs is a privately held company funded by Toba Capital, Salesforce Ventures, Centerview Capital Technology, IVP and Adams Street Partners. For more information, please visit saucelabs.com.
